## Chapter 1

## Assignment 1.16

### 1.1 Part a

Assume $a_{7}, b_{7}$ and $s_{7}$ are the sign bits of a two complements summator, addendum and result respectively. Than an overflow $v$ in the adder occures in case the result is negative whilst the summator and addendum are both positive, or in case the result is positive whilst the summator and addendum are both negative. So $v$ is defined as formulated in Equation 1.1.

$$
\begin{align*}
v & =s_{7} \cdot \overline{a_{7}} \cdot \overline{b_{7}}+\overline{s_{7}} \cdot a_{7} \cdot b_{7} \\
& =s_{7} \cdot \overline{\left(a_{7}+b_{7}\right)}+\overline{s_{7}} \cdot g_{7}  \tag{1.1}\\
& =s_{7} \cdot \overline{t_{7}}+\overline{s_{7}} \cdot g_{7}
\end{align*}
$$

For the two's complement addition the summation is defined as in Equation 1.2, and the carry out of a bit position is defined as in Equation 1.3.

$$
\begin{gather*}
s_{7}=p_{7} \cdot \overline{c_{7}}+\overline{p_{7}} \cdot c_{7} \Leftrightarrow \overline{s_{7}}=\overline{p_{7}} \cdot \overline{c_{7}}+p_{7} \cdot c_{7}  \tag{1.2}\\
c_{8}=g_{7}+t_{7} \cdot c_{7} \Leftrightarrow \overline{c_{8}}=\overline{t_{7}}+\overline{g_{7}} \cdot \overline{c_{7}} \tag{1.3}
\end{gather*}
$$

Substitution of Equation 1.2 into Equation 1.1, and the knowledge that $\overline{t_{7}} \cdot p_{7}=$ 0 , and $g_{7} \cdot p_{7}=0$, delivers:

$$
\begin{align*}
v & =\overline{t_{7}} \cdot p_{7} \cdot \overline{c_{7}}+\overline{t_{7}} \cdot \overline{p_{7}} \cdot c_{7}+ \\
& =\overline{g_{7}} \cdot \overline{p_{7}} \cdot \overline{c_{7}}+c_{7}+g_{7} \cdot \overline{g_{7}} \cdot p_{7} \cdot c_{7} \tag{1.4}
\end{align*}
$$

By introducing the terms $\overline{g_{7}} \cdot \overline{c_{7}} \cdot c_{7}$ and $t_{7} \cdot c_{7} \cdot \overline{c_{7}}$, which both equal to 0 , into Equation 1.4, and the usage of Equation 1.3, we see that:

$$
\begin{align*}
v & =c_{7} \cdot\left(\overline{t_{7}}+\overline{g_{7}} \cdot \overline{c_{7}}\right)+\overline{c_{7}} \cdot\left(g_{7}+t_{7} \cdot c_{7}\right) \\
& =c_{7} \cdot \overline{c_{8}}+\overline{c_{7}} \cdot c_{8}  \tag{1.5}\\
& =c_{7} \oplus c_{8}
\end{align*}
$$

QED.

### 1.2 Part b

For one's complement numbers the sommation $S$ of two one's complement numbers A and B, is defined as $S=A+B$ when $c_{o u t}=0$ and $S=A+B+1$ when $c_{o u t}=1$. We clearly see a non-linearity in the definition of the one's complement summation function. For simplicity let's assume that $c_{i n}=0$. It can easily being showed that the following discussion also holds in case $c_{i n}=1$. Taking the definition of the one's complement summation, we can build a one's complement adder by using a two's complement adder in a "feedback" configuration as shown in Figure 1.1.

Figure 1.1: One's complement adder build from a Two's complement feedback adder

It can be shown that the one's complement adder of Figure 1.1 stabalizes very quickly, and thus does not form an oscillator. For simplicity let's assume that our A, B and S terms are three-bits one's complement numbers. It can be shown that the following discussion holds for any n-bits one's complement numbers. Under the assumption of the three-bits one's complement numbers we can build a one's complement adder, from the one shown in Figure 1.1, as the two shown in Figure 1.2. Note that the adder shown on the left produces exactly the same result as the one shown on the right!

Figure 1.2: Three bits one's complement adder
In Figure 1.2 V denotes the Overflow output. We also know that the summation is lineair and symetric, e.g. $S=A+B \Leftrightarrow S=B+A$. Table 1.1 list all possible one's complement additions, and clearly shows that $v=c_{2} \oplus c_{3}$ is the definition for the overflow in a one's complement addition. Note that the numbers shown underlined are the real outputs of the one's complement addition.

Table 1.1: All three bits one's complement additions

## Chapter 2

## Assignment 2.18

### 2.1 Part a

From Lings summation and propagate function we know that:

$$
\begin{equation*}
s_{i}=t_{i} \cdot \overline{h_{i}}+\overline{t_{i}} \cdot h_{i}+g_{i} \cdot t_{i-1} \cdot h_{i-1} \tag{2.1}
\end{equation*}
$$

and:

$$
\begin{equation*}
h_{i}=g_{i}+t_{i-1} \cdot h_{i-1} \Leftrightarrow \overline{h_{i}}=\overline{g_{i}} \cdot \overline{t_{i-1}}+\overline{g_{i}} \cdot \overline{h_{i-1}} \tag{2.2}
\end{equation*}
$$

Using these both Equations, and the knowledge that $\overline{t_{i}} \cdot g_{i}=0$, we find:

$$
\begin{align*}
s_{i} & =\frac{t_{i}}{} \cdot \overline{g_{i}} \cdot \overline{t_{i-1}}+t_{i} \cdot \overline{g_{i}} \cdot \overline{h_{i-1}}+\overline{t_{i}} \cdot g_{i}+ \\
& \overline{t_{i}} \cdot t_{i-1} \cdot h_{i-1}+g_{i} \cdot t_{i-1} \cdot h_{i-1} \\
& =t_{i} \cdot \overline{g_{i}} \cdot\left(\overline{t_{i-1}}+\overline{h_{i-1}}\right)+\left(\overline{t_{i}}+g_{i}\right) \cdot t_{i-1} \cdot h_{i-1}  \tag{2.3}\\
& =p_{i} \cdot \overline{\left(t_{i-1} \cdot h_{i-1}\right)}+\overline{p_{i}} \cdot t_{i-1} \cdot h_{i-1} \\
& =p_{i} \oplus\left(t_{i-1} \cdot h_{i-1}\right)
\end{align*}
$$

By definition we know that:

$$
\begin{equation*}
h_{i}=g_{i}+t_{i-1} \cdot h_{i-1}=c_{i+1}+c_{i} \tag{2.4}
\end{equation*}
$$

and:

$$
\begin{equation*}
c_{i+1}=g_{i}+p_{i} \cdot c_{i}=g_{i}+t_{i} \cdot c_{i} \tag{2.5}
\end{equation*}
$$

Using both equations results in:

$$
\begin{equation*}
g_{i}+t_{i-1} \cdot h_{i-1}=g_{i}+t_{i} \cdot c_{i}+c_{i} \Leftrightarrow g_{i}+t_{i-1} \cdot h_{i-1}=g_{i}+c_{i} \Rightarrow c_{i}=t_{i-1} \cdot h_{i-1} \tag{2.6}
\end{equation*}
$$

As $c_{i}=t_{i-1} \cdot h_{i-1}$ and Lings summation is $s_{i}=p_{i} \oplus\left(t_{i-1} \cdot h_{i-1}\right)$ this results in $s_{i}=p_{i} \oplus c_{i}$ which is the definition of the addition, QED.

### 2.2 Part b

The recursions for the adder generation for a conventional adder and a Ling adder for a group of four is shown in the Table below.
We know that a $t_{i}$ term has a fanin of 1 , and a $g_{i}$ term has a fanin of 2 . We can clearly see from the Table presented that the Ling recursion removes one

| Conventional carry: | Conventional sum: | Ling carry: | Ling sum: |
| :---: | :---: | :---: | :---: |
| $c_{1}=g_{0}+t_{0} \cdot c_{0}$ | $s_{0}=p_{0} \oplus c_{0}$ | $h_{0}=g_{0}+c_{0}$ | $s_{0}=p_{0} \oplus c_{0}$ |
| $c_{2}=g_{1}+t_{1} \cdot g_{0}+t_{1} \cdot t_{0} \cdot c_{0}$ | $s_{1}=p_{1} \oplus c_{1}$ | $h_{1}=g_{1}+g_{0}+t_{0} \cdot c_{0}$ | $s_{0}=p_{1} \oplus\left(h_{0} \cdot t_{0}\right)$ |
| $c_{3}=g_{2}+t_{2} \cdot g_{1}+t_{2} \cdot t_{1} \cdot g_{0}+$ | $s_{2}=p_{2} \oplus c_{2}$ | $h_{2}=g_{2}+g_{1}+t_{1} \cdot g_{0}+$ | $s_{2}=p_{2} \oplus\left(h_{1} \cdot t_{1}\right)$ |
| $t_{2} \cdot t_{1} \cdot t_{0} \cdot c_{0}$ |  | $t_{1} \cdot t_{0} \cdot c_{0}$ |  |
| $c_{4}=g_{3}+t_{3} \cdot g_{2}+t_{3} \cdot t_{2} \cdot g_{1}+$ |  | $h_{3}=g_{3}+g_{2}+t_{2} \cdot g_{1}+$ |  |
| $t_{3} \cdot t_{2} \cdot t_{1} \cdot g_{0}+$ | $s_{3}=p_{3} \oplus c_{3}$ | $t_{2} \cdot t_{1} \cdot g_{0}+$ | $s_{3}=p_{3} \oplus\left(h_{2} \cdot t_{2}\right)$ |
| $t_{3} \cdot t_{2} \cdot t_{1} \cdot t_{0} \cdot c_{0}$ | $t_{2} \cdot t_{1} \cdot t_{0} \cdot c_{0}$ |  |  |
| $c_{\text {out }}=c_{4}$ |  | $c_{\text {out }}=h_{3} \cdot t_{3}$ |  |

product term of each sum-term of the carry generation, and bubbles it towards the sum calculation. For $s_{0}$ we clearly see that there is no difference between the conventional and the Ling adder, as both have no carry generation, and for the sum we have the same structure. For $s_{1}$ we see also that there is no difference, as the conventional carry generation uses a fanin scheme of $[2,2]$, whilst the Ling uses a scheme of $[1,1]$. In the sum generation the normal scheme is $[1,1]$, whilst the Ling must use here [2,2], making the area and fanin of both scheme's equal. For $s_{2}$ we see the first advantage of Ling, the normal carry generation uses here a $[2,3,3]$ scheme, whilst the Ling uses a $[2,2,2]$ scheme. In the summation the normal scheme we still find $[1,1,1]$, whilst the ling gives a [1,3,2] scheme. Overall, we can say that Ling removes here 2 "AND" product terms in the carry generation, and introduces one in the sum generation, which results in the area savings of one "AND" product term, and a fanin saving of 1. Equally for $s_{3}$ the Ling recursion removes 3 "AND" product terms in the carry generation, and intruduces one in the sum generation, which results in the area savings of two "AND" product terms, and a fanin saving of 2. Finally for the carry out generation the Ling saves four "AND" product tems, and only intruduces one in the carry out generation. Thus saving 3 "AND" produc terms, and a fanin saving of 3 .
We can see that Ling saves a total of 6 "AND" product terms in Area and a total of 6 fanin savings, when we look at a block of four bits.

## Chapter 3

## Assignment 2.21

Denote $g_{i}=a_{i} \cdot b_{i}$ and $p_{i}=a_{i} \oplus b_{i}$. For the carry we get $c_{i+1}=g_{i}+p_{i} \cdot c_{i-1}$ and for the sum $s_{i}=p_{i} \oplus c_{i}$. When we consider the prefix adders than we can formulate:

$$
\begin{array}{r}
c_{1}=g_{0}+p_{0} \cdot c_{0} \\
c_{2}=g_{1}+p_{1} \cdot c_{1}=\left(g_{1}+p_{1} \cdot g_{0}\right)+\left(p_{1} \cdot p_{0}\right) \cdot c_{0}=G_{1}+P_{1} \cdot c_{0} \\
c_{3}=g_{2}+p_{2} \cdot c_{2}=\left(g_{2}+p_{2} \cdot G_{1}\right)+\left(p_{2} \cdot P_{1}\right) \cdot c_{0}=G_{2}+P_{2} \cdot c_{0} \\
c_{n+1}=g_{n}+p_{n} \cdot c_{n}=\left(g_{n}+p_{n} \cdot G_{n-1}\right)+\left(p_{n} \cdot P_{n-1}\right) \cdot c_{0}=G_{n}+P_{n} \cdot c_{0} \tag{3.4}
\end{array}
$$

And Thus:

$$
\begin{equation*}
s_{n}=p_{n} \oplus c_{n}=p_{n} \oplus\left(G_{n-1}+P_{n-1} \cdot c_{0}\right) \tag{3.5}
\end{equation*}
$$

In case we have $c_{0}=0$ this reduces to $s_{n}=p_{n} \oplus G_{n-1}$ the well known prefix equation, and result for the requested $s=x+y$ addition. In case $c_{0}=1$ this equation states: $s_{n}=p_{n} \oplus\left(G_{n-1}+P_{n-1}\right)$ which can be implemented by only one extra stage, and which delivers the result for the requested $z=x+y+1$ addition. This means that by only adding n-"OR" gates and n-"XOR" gates we can determine $s=x+y$ and $z=x+y+1$ with the same prefix adder, which has no carry in functionality.

## Chapter 4

## Assignment 3.24

### 4.1 Part a

We can determine the range of results by taking $\min |z|=-4-3 \cdot 3+5$. $(-4)=-33$ and $\max |z|=3-3 \cdot(-4)+5 \cdot 3=30$. Using two's complement representation, the value 30 can be represented in 6 bits, but the value -33 needs 7 bits to be represented. The least number of bits to represent $z$ is therefore 7 .

### 4.2 Part b

We can rewrite the summation as: $z=a-4 b+b+4 c+c$. The bit-matrix for this sommation is (as $\mathrm{a}, \mathrm{b}$ and c are representable in three bits):

| $a_{2}$ | $a_{2}$ | $a_{2}$ | $a_{2}$ | $a_{2}$ | $a_{1}$ | $a_{0}$ | a |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $b_{2}$ | $b_{2}$ | $b_{2}$ | $b_{2}$ | $b_{2}$ | $b_{1}$ | $b_{0}$ | b |
| $\overline{b_{2}}$ | $\overline{b_{2}}$ | $\overline{b_{2}}$ | $\overline{b_{1}}$ | $\overline{b_{0}}$ | 0 | 0 | -4 b |
| 0 | 0 | 0 | 0 | 1 | 0 | 0 |  |
| $c_{2}$ | $c_{2}$ | $c_{2}$ | $c_{2}$ | $c_{2}$ | $c_{1}$ | $c_{0}$ | c |
| $c_{2}$ | $c_{2}$ | $c_{2}$ | $c_{1}$ | $c_{0}$ | 0 | 0 | 4 c |

It can be shown that $\left\{a_{2}, a_{2}, a_{2}, a_{2}, a_{2}, a_{1}, a_{0}\right\}=\{1,1,1,1,1,0,0\}+\left\{0,0,0,0, \overline{a_{2}}, a_{1}, a_{0}\right\}$ for sign extenstions. Usign this property results in the first optimizations shown in Table 4.1. Know we can add all constants to form one constant value, as shown in Tables 4.2, 4.3 and 4.4. Finally by rewriting Table 4.4 a little bit we achieve the final bit-matrix shown in Table 4.5.

### 4.3 Part c

Taking Table 4.5 We can use 5 Full Adders (0..4) to form the reduced Matrix shown in Table 4.6. For the next reduction we can use FA (5) for the row of four, and we can again use two HA's (6..7) to form the reduced Matrix Show in Table 4.7.

The schematic of the realised adder is depicted in Figure 4.1.

| 0 | 0 | 0 | 0 | $\overline{a_{2}}$ | $a_{1}$ | $a_{0}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 1 | 1 | 1 | 1 | 0 | 0 |
| 0 | 0 | 0 | 0 | $\overline{b_{2}}$ | $b_{1}$ | $b_{0}$ |
| 1 | 1 | 1 | 1 | 1 | 0 | 0 |
| 0 | 0 | $b_{2}$ | $\overline{b_{1}}$ | $\overline{b_{0}}$ | 0 | 0 |

| 0 | 0 | $\overline{c_{2}}$ | $c_{1}$ | $c_{0}$ | 0 | 0 |
| 1 | 1 | 0 | 1 | 1 | 0 | 0 |

Table 4.2: Second table optimization

### 4.4 Part d

The minimal precision of the CPA in Figure 4.1 is 5 bits, as the lsb is directly provided by the csa-tree, and the sign bit is the inverse of the carry out of the CPA, as result of the constant ' 1 ' on position 6 in Table 4.7. The best suited CPA would be a carry-select based CPA.

| 0 | 0 | 0 | 0 | $\overline{a_{2}}$ | $a_{1}$ | $a_{0}$ |

## Chapter 5

## Assignment 4.18

### 5.1 Part a

Asume that the $12 \times 12$ two's complement multiplication is defined as $M=A$, where $M$ is the multiplication result, $A$ is the multiplier and $B$ is the multiplicant. The bit-matrix for this multiplication without sign reduction, and the matrices for the $5 \times 5$ two's complement multiplication are shown in Figure 5.1. The number of $5 \times 5$ multiply modules needed are 9 .
