FIR FILTER HARDWARE

FIR Filter Review

• FIR filters are calculated by convolution

$$y(n) = \sum_{k=-\infty}^{+\infty} x(k)h(n-k)$$

•
$$y(n) = x_n h_2 + x_{n+1} h_1 + x_{n+2} h_0$$

• A "full" non-iterative direct-form FIR filter with a throughput of one sample per cycle adds the products of each coefficient times a delayed version of the input

 For direct-form FIR filters which add multiple products into an output sum, an efficient implementation adds all products in a single large multiple-input adder using the efficient carry-save adders → carry-propagate adder structure

 In the common case when the *h* coefficients are fixed, there is of course no change and no downside if the "always zero" partial products are removed

- In the single large multiple-input adder, partial products from all filter taps get merged with each other in one large "pile of dots" where we no longer need to distinguish from which *x*(*n*) and *h*(*n*) a dot came
- The dots are added with a single carry-save adder structure in a manner similar to how multiplier partial-products are reduced

• A carry-propagate adder finally reduces the *y* filter output to a single word

FIR Filter HW Reduction

- If we can scale all coefficients by the same amount
 - It may be possible to reduce a filter's complexity significantly if we can find *h*(*n*) values with more zero partial products
 - The frequency response will be unchanged
 - The overall filter output magnitude *is* changed
 - Must watch out for:
 - Overflow—if the filter's output is scaled larger
 - Quantization noise—if the filter's output is scaled smaller

FIR Filter Scaling

Partial products: 2 2 4 2 2

• If coeffs = [9 18 45 18 9] note that 0.889 x coeffs = [8 16 40 16 8]

Partial products: 1 1 2 1 1

FIR Filter Scaling

- Often, scaling of a filter can be
 - ignored, or
 - accommodated or compensated elsewhere in the signal path

FIR Output Worst-Case

- Worst-case inputs: maximum pos/neg samples
 - Signs of input samples match coefficient signs
 - Signs of input samples are opposite of coefficient signs

FIR Output Growth

- As filter lengths increase, the peak-to-average ratio can get very large. Possible solutions include:
 - Widen the widths of all words so that the full range output can be accommodated
 - Can be unnecessary and wasteful of hardware and energy
 - Overflow
 - Almost certainly risky and a very bad idea
 - Saturation or Compression
