Fundamentals of Wireless Communications

- ◆ #1: Frequencies
- ◆ #2: Radio Propagation Model
- ◆ #3: Modulation

Acknowledgment: Selected slides from Prof. Schiller & Prof. Goldsmith

Characteristics of Wireless Medium

- Comparison to wired media
 - Unguided link
 - Unreliable
 - Low bandwidth
 - Untethered: supports mobility
 - Broadcast nature
 - Shared medium
 - Capacity limitation
- Frequency of operation and legality of access differentiates a variety of alternatives for wireless networking

2

Frequencies for Communication

VLF = Very Low Frequency UHF = Ultra High Frequency
 LF = Low Frequency SHF = Super High Frequency
 MF = Medium Frequency EHF = Extra High Frequency
 HF = High Frequency UV = Ultraviolet Light
 VHF = Very High Frequency

Frequency and wave length: $\lambda = c/f$

- Wave length λ , speed of light $c \cong 3 \times 10^8 \text{ m/s}$, frequency f

3

Frequencies for Mobile Communication

- VHF-/UHF-ranges for mobile radio
 - Simple, small antenna for cars
 - Deterministic propagation characteristics, reliable connections
- SHF and higher for directed radio links, satellite communication
 - Small antenna, focusing
 - Large bandwidth available
- Wireless LANs use frequencies in UHF to SHF spectrum
 - Some systems planned up to EHF
 - Limitations due to absorption by water and oxygen molecules (resonance frequencies)
 - Weather dependent fading, signal loss caused by heavy rainfall etc.

4

Operational Ranges

- 1 GHz (cellular)
- 2 GHz (PCS and WLAN)
- 5 GHz (WLANs)
- 28-60 GHz (local multipoint distribution services (LMDS) and point-to-point base-station connections)
- IR frequencies for optical communications

5

Licensed and Unlicensed Bands

- Licensed:
 - Cellular/PCS
 - Expensive (PCS bands in US were sold for around \$20B)
 - Time consuming to deploy new applications rapidly at low costs
- Unlicensed:
 - Industrial, Medical, and Scientific (ISM) Bands
 - Free, component costs are also low
 - New applications such as WLAN, Bluetooth are easily developed
- With the increase in frequency and data rate, the hardware cost increases, and the ability to penetrate walls also decreases

6

Frequencies and regulations

	Europe	USA	Japan
Cellular Phones	GSM 450-457, 479-486/460-467, 489-496, 890-915/935-960, 1710-1785/1805-1880 UMTS (FDD) 1920-1980, 2110-2190 UMTS (TDD) 1900-1920, 2020-2025	AMPS, TDMA, CDMA 824-849, 869-894 TDMA, CDMA, GSM 1850-1910, 1930-1990	PDC 810-826, 940-956, 1429-1465, 1477-1513
Cordless Phones	CT1+ 865-867, 930-932 CT2 864-868 DECT 1880-1900	PACS 1850-1910, 1930-1990 PACS-UB 1910-1930	PHS 1895-1918 JCT 254-380
Wireless LANs	IEEE 802.11 2400-2483 HIPERLAN 2 5150-5350, 5470-5725	902-928 IEEE 802.11 2400-2483 5150-5350, 5725-5825	IEEE 802.11 2471-2497 5150-5250
Others	RF-Control 27, 128, 418, 433, 868	RF-Control 315, 915	RF-Control 426, 868

7

Radio Propagation

- Three most important radio propagation characteristics used in the design, analysis, and installation of wireless networks are:
 - Achievable signal coverage
 - Maximum data rate that can be supported by the channel
 - Rate of fluctuations in the channel

8

Signals - 1

- Physical representation of data
- Function of time and location
- Signal parameters: parameters representing the value of data
- Classification
 - Continuous time/discrete time
 - Continuous values/discrete values
 - Analog signal = continuous time and continuous values
 - Digital signal = discrete time and discrete values
- Signal parameters of periodic signals: period T , frequency $f=1/T$, amplitude A , phase shift ϕ
 - sine wave as special periodic signal for a carrier:

$$s(t) = A_i \sin(2\pi f_i t + \phi_i)$$

9

Fourier representation of periodic signals

$$g(t) = \frac{1}{2}c + \sum_{n=1}^{\infty} a_n \sin(2\pi n f t) + \sum_{n=1}^{\infty} b_n \cos(2\pi n f t)$$

10

Signals - 2

- Different representations of signals
 - Amplitude (amplitude domain)
 - Frequency spectrum (frequency domain)
 - Phase state diagram (amplitude M and phase ϕ in polar coordinates)

11

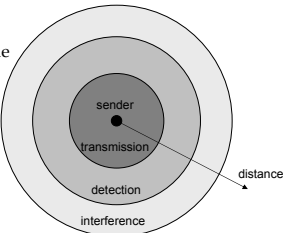

Signal - 3

- Composed signals transferred into frequency domain using Fourier transformation
- Digital signals need
 - infinite frequencies for perfect transmission
 - modulation with a carrier frequency for transmission (analog signal!)

12

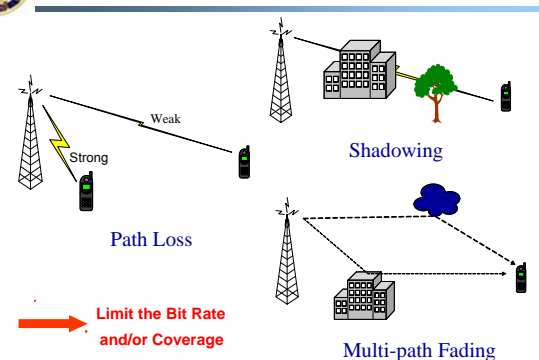

Signal propagation ranges

- Transmission range
 - Communication possible
 - Low error rate
- Detection range
 - Detection of the signal possible
 - No communication possible
- Interference range
 - Signal may not be detected
 - Signal adds to the background noise

13

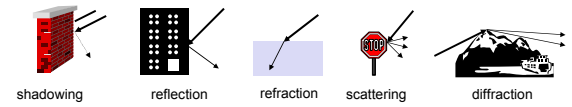

Radio Environment

14

A. Path Loss of Radio Signal

- Signal propagation in free space always like light (straight line)
- Receiving power proportional to $1/d^2$ (d = distance between sender and receiver)
- Receiving power additionally influenced by
 - Fading (frequency dependent)
 - Shadowing
 - Reflection at large obstacles
 - Refraction depending on the density of a medium
 - Scattering at small obstacles
 - Diffraction at edges

15

Path Loss Model (1)

- Many path loss models
 - Analytical, empirical (fitting curves to measured data), or combination.
- A general model for path loss (or sometimes referred to as path gain), L , is:

$$L = \frac{\bar{P}_r}{P_t} = G_t G_r \frac{1}{k(4\pi)^2 f^2 d^\alpha}$$

where \bar{P}_r is the local mean received signal power
 P_t is the transmitted power
 d is the transmitter-receiver distance,
 f is frequency
 G_t, G_r are transmitter and receiver antennae gains
 k is a loss factor not related to propagation

The path loss exponent: $2 \leq \alpha \leq 4$ ($\alpha = 2$ in free space)

16

Path Loss Model (2)

- We can simplify things by lumping the constant together:

$$L = K \left(\frac{1}{f^2 d^\alpha} \right)$$

- In practice, one can measure the power received at a reference point, d_o from the transmitted and estimate P_r as:

$$P_r = P_o \left(\frac{d}{d_o} \right)^{-\alpha}$$

$$P_r(\text{dBm}) = P_o(\text{dBm}) - 10\alpha \log \left(\frac{d}{d_o} \right)$$

- Free space propagation model: $\alpha = 2$
 - Used when transmitter and receiver has clear, unobstructed, line-of-sight (LOS) path
- For shadow urban, $\alpha = 4$

(Example link budget calculation: slides # 35-36)

17

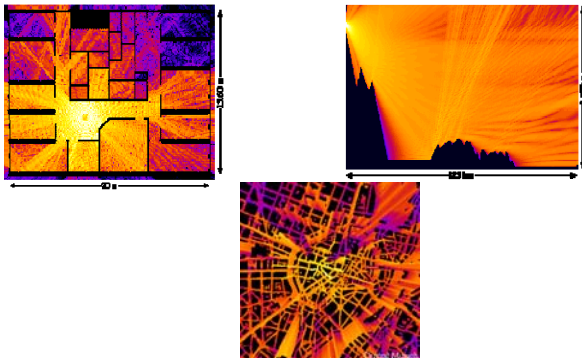

Radio Propagation Mechanisms

- Reflection and Transmission:
 - Upon reflection or transmission, the radio signals attenuates by factors that depend on the frequency, angle of incidence, and the nature of medium
- Diffraction:
 - Diffracted fields are generated by secondary wave sources formed at the edges of the buildings, walls, and other large objects. Diffraction facilitates the reachability of signals that are not in line of sight of the transmitter. However, the losses are more than that of reflection and transmission
- Scattering:
 - Irregular surfaces scatter signals in all directions in the form of spherical waves. Propagation in many directions results in reduced power levels.

18

Real World Example

19

B. Shadow fading

- Received signal is shadowed by obstructions such as hills and buildings.
- Depending on the environment and the surroundings, and the location of objects, the received signal strength for the same distance from the transmitter will be different. This variation of signal strength due to location is referred to as shadow fading
- This results in variations in the local mean received signal power

$$P_r(\text{dB}) = P_t(\text{dB}) + G_s$$

where $G_s \sim N(0, \sigma_s^2)$, $4 \leq \sigma_s \leq 10 \text{ dB}$.

20

B. Shadow Fading - Implications

- Non-uniform coverage
- Increases the required transmit power
 - To overcome the shadow fading effects, a fade margin is added to the path loss or received signal strength. The fade margin is the additional signal power that can provide a certain fraction of the locations with the required signal strength

21

C. Multipath propagation

- Signal can take many different paths between sender and receiver due to reflection, scattering, diffraction

22

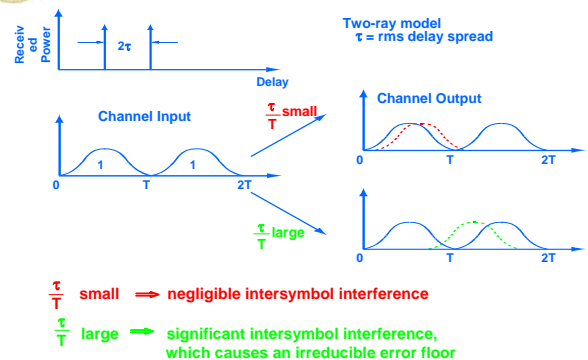

Multipath propagation – Cont'd

- Time dispersion: signal is dispersed over time
 - Interference with “neighbor” symbols
 - Inter Symbol Interference (ISI)
- The signal reaches a receiver directly and phase shifted
 - Distorted signal depending on the phases of the different parts

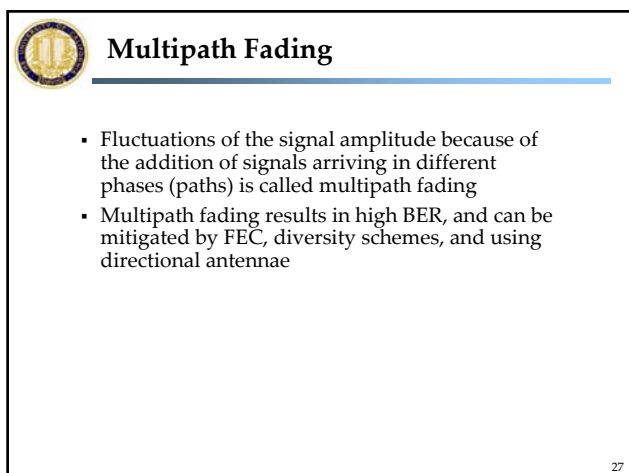

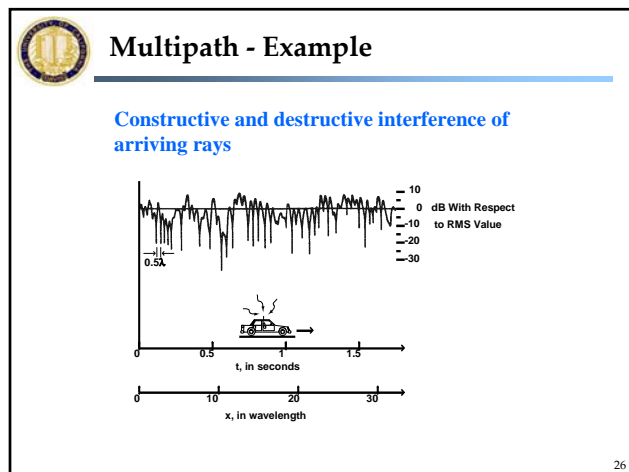

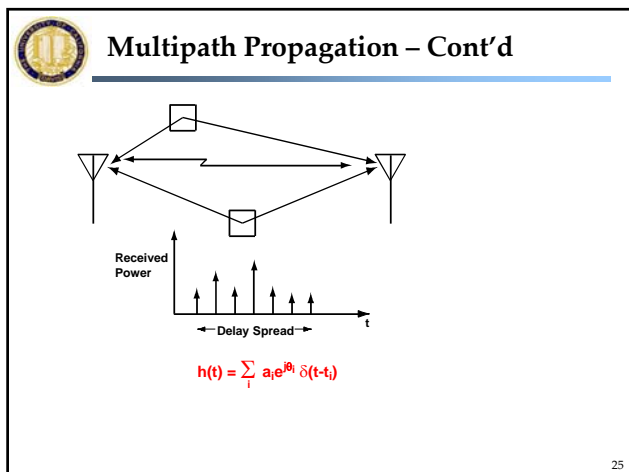

23

Delay Spread

24

Doppler Shift

- Doppler Shift, f_d
 - Apparent change in frequency due to movement

$$f_d = \frac{1}{2\pi} \cdot \frac{\Delta\phi}{\Delta t} = \frac{v}{\lambda} \cdot \cos\theta$$

- If mobile is moving toward the direction of arrival of the wave, the Doppler shift is positive
- If the mobile is moving away, the Doppler shift is negative
- Max shift when angle = 0 (moving directly toward/away transmitter)

29

Time-varying Channel Conditions

- Due to users' mobility and variability in the propagation environment, both desired signal and interference are **time-varying and location-dependent**

- A measure of channel quality:

SNR (Signal to Noise Ratio)

$$SNR = \frac{\text{Desired Signal Power}}{\text{Noise power}} = \frac{P_r}{N}$$

- Desired signal power = received power = P_r
 - We know how to estimate this from slide #17
- Background noise, e.g., thermal noise
 - Simple model: Noise power = ηW , where η is the average power per Hertz of the thermal noise, and W is the signal bandwidth

30

Time-varying Channel Conditions

- A more complete measure of channel quality:

SINR (Signal to Interference plus Noise Ratio)

$$SINR = \frac{\text{desired signal power}}{\text{interference power} + \text{background noise power}}$$

- In the impact of interference is much more than noise, another measure is carrier-to-interference (C/I) ratio, i.e., assuming noise power is close to zero
- We will talk about how to estimate 'Interference' in the next lecture

31

Illustration of Channel Conditions

32

Physical Layer Issues

- Practical Link Performance Measures
 - Probability of Bit Error (BER)
 - Efficiency
- Modulation Tradeoffs
- Flat Fading Countermeasures
- Delay Spread Countermeasures

EEEC165, EEC166
EEEC265, EEC266

33

Link Performance Measure (1): BER

- The probability of bit error, P_b , in a radio environment is a random variable
 - Average P_b (\bar{P}_b)
 - $P_r [P_b > P_{b,target}] \triangleq \text{outage } (P_{out})$
- Bit-error-rate is a function of SNR (signal-to-noise-ratio), or C/I (carrier-to-interference ratio), at the receiver
 - The function itself depends on the modulation

34

Calculate 'Link Budget' using Path Loss Models

- Link budget calculation requires
 - Estimate of power received from transmitted at a receiver
 - Estimate of noise & power received from "interferers"
 - For example, $SNR \text{ (dB)} = P_r \text{ (in dBm)} - N \text{ (in dBm)}$
- Recall on slide #17,

$$P_r = P_o \left(\frac{d}{d_o} \right)^{-\alpha} \Rightarrow P_r \text{ (dBm)} = P_o \text{ (dBm)} - 10\alpha \log \left(\frac{d}{d_o} \right)$$
- Typical approximation
 - d is the distance between transmitter and receiver measured relative to the reference point d_o
 - α is the path-loss exponent
 - P_o is a constant that accounts for antenna gains, carrier frequency, and reference point d_o

35

Example Link Budget calculation

- Maximum separation distance vs. transmitted power (with fixed BW)
 - Given:
 - Cellular phone with 0.6 W transmit power
 - Unity gain antenna, 900 MHz carrier frequency
 - SNR must be at least 25dB for proper reception
 - Noise = -119 dBm
 - Assume path loss constant, $\alpha=2$, and P_o (at $d_o=1\text{km}$) = -63.5 dBm
 - What will be the maximum distance?

36

Link Performance Measure (2): Efficiency

- **Spectral Efficiency:** a measure of the data rate per unit bandwidth for a given bit error probability and transmitted power
- **Power Efficiency:** a measure of the required received power to achieve a given data rate for a given bit error probability and bandwidth
- **Throughput/Delay**

37

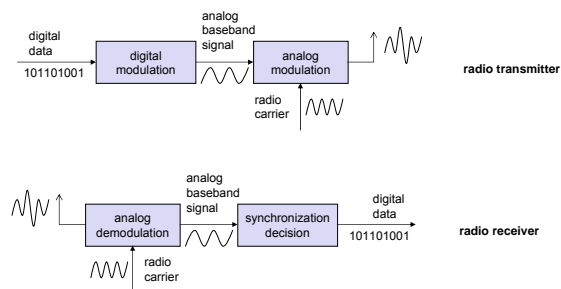

Modulation - 1

- Digital modulation
 - Digital data is translated into an analog signal (baseband)
- Analog modulation
 - Shifts center frequency of baseband signal up to the radio carrier
- Basic schemes
 - Amplitude Modulation (AM)
 - Frequency Modulation (FM)
 - Phase Modulation (PM)

38

Modulation and Demodulation

39

Digital modulation

- Modulation of digital signals known as Shift Keying
- Amplitude Shift Keying (ASK):
 - Very simple
 - Low bandwidth requirements
 - Very susceptible to interference
- Frequency Shift Keying (FSK):
 - Needs larger bandwidth
- Phase Shift Keying (PSK):
 - More complex
 - Robust against interference

40

Grouping the Information Bits into Symbols

b bits/symbol = M possible waveforms

1 bit/symbol

2 bits/symbol

- If $M \rightarrow \infty$ the 'performance' goes up, but at a cost of complexity (Shannon limit)

41

Signal Space Representation

- The basic idea is that we can transmit information in parallel over a set of **orthogonal waveforms** with respect to the symbol interval **T**. The inverse of this interval is called the symbol rate: **$R_s = 1/T$** .

$$\int_{t=0}^T s_1(t) \cdot s_2(t) dt = \delta_{ij}$$

42

Detection of the Symbols

- Correlation or matched filter detector (basically equivalent)

Sample at $t = T$

$$\int_{t=0}^T s_1(t) \cdot s_2(t) dt = \delta_{ij}$$

=> Look at example waveform in HW 1

43

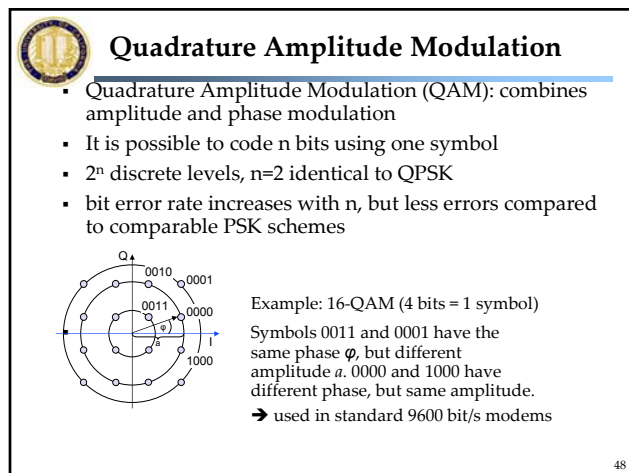

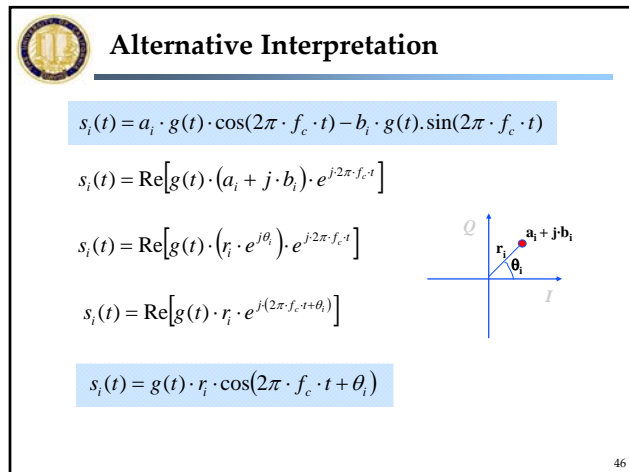

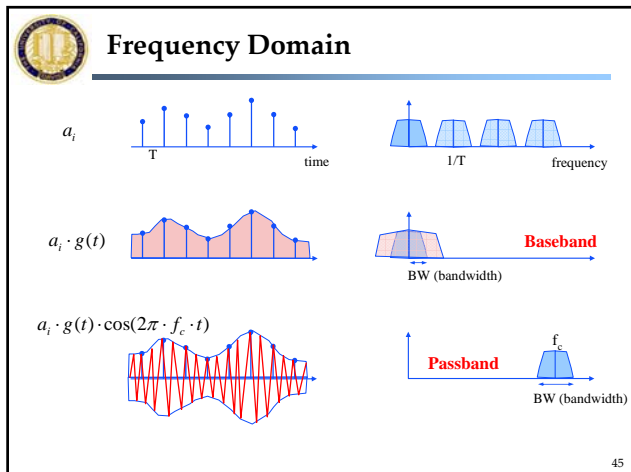

Digital Modulation

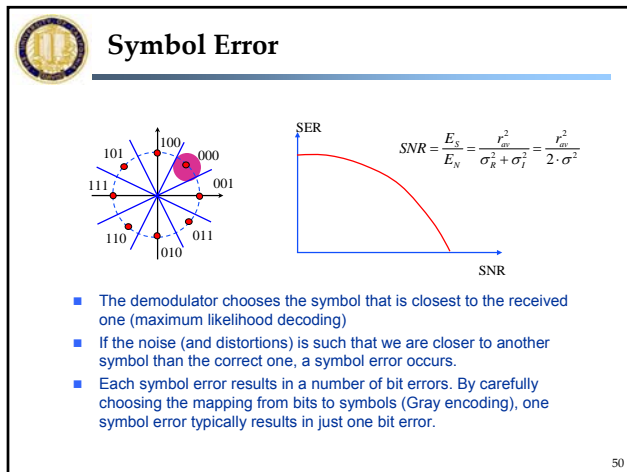

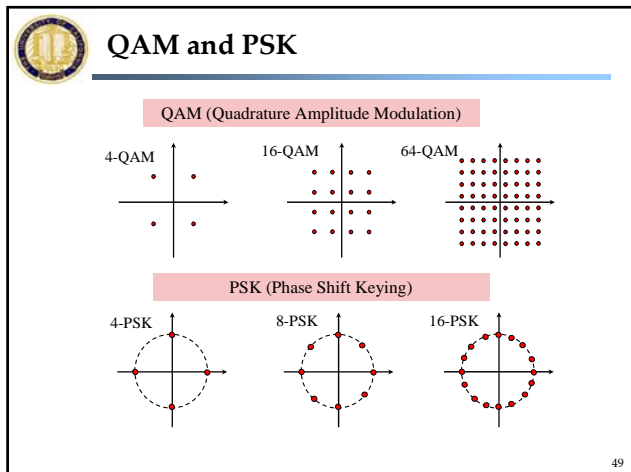

- Any modulated signal can be represented as

$$s(t) = \underbrace{A(t)}_{\text{amplitude}} \underbrace{\cos[\omega_c t + \phi(t)]}_{\text{phase or frequency}}$$

$$= \underbrace{A(t) \cos \phi(t)}_{\text{in-phase}} \cos \omega_c t - \underbrace{A(t) \sin \phi(t)}_{\text{quadrature}} \sin \omega_c t$$
- Linear versus nonlinear modulation
=> **Impact on spectral efficiency**
- Constant envelope versus non-constant envelope
=> **hardware implications with impact on power efficiency**

44

Advanced Frequency Shift Keying

- Bandwidth needed for FSK depends on the distance between the carrier frequencies
- Special pre-computation avoids sudden phase shifts
 - ➔ MSK (Minimum Shift Keying)
 - Bit separated into even and odd bits, the duration of each bit is doubled
 - Depending on the bit values (even, odd) the higher or lower frequency, original or inverted is chosen
 - The frequency of one carrier is twice the frequency of the other
- Equivalent to offset QPSK
- Even higher bandwidth efficiency using a Gaussian low-pass filter
 - ➔ GMSK (Gaussian MSK), used in GSM

51

Selecting a Modulation Scheme (1)

- High Bit Rate
- Robustness to Impairments
 - Provides low bit error rates (BER) at low signal-to-noise ratios (SNR)
 - Performs well in multipath fading
 - Performs well in time varying channels (symbol timing jitter)
- High Spectral Efficiency: occupies minimal bandwidth
- High Power Efficiency
- Low cost and easy to implement
- Low carrier-to-cochannel interference ratio
- Low out of band radiation
- Constant or near-constant "envelope"
 - constant: only phase is modulated
 - may use efficient non-linear amplifiers
 - non-constant: phase and amplitude modulated
 - may need inefficient linear amplifiers

53

Selecting a Modulation Scheme (2)

- Other design rationale
 - Smaller antennas (e.g., $\lambda/4$)
 - Frequency Division Multiplexing
 - Medium characteristics

No perfect modulation scheme - a matter of trade-offs!

Two metrics:

- Energy efficiency E_b/N_0 for a certain BER and
- Bandwidth efficiency R/B

54

Receiver Performance

55

Energy-Bandwidth Trade-off

	E_b/N_0	BW Eff.
BPSK	9.09	1
QPSK	9.09	2
8-PSK	19.82	3
16-PSK	55.41	4
32-PSK	171.20	5
8-QAM	13.93	3
16-QAM	22.05	4
32-QAM	34.67	5
BFSK	17.78	1
4-FSK	9.77	1
8-FSK	7.08	0.75
16-FSK	5.62	0.5
32-FSK	4.52	0.3125
GMSK	10	1.35

56
